NATIONAL BUREAU OF ECONOMIC RESEARCH 1050 Massachusetts Avenue Cambridge, MA 02138 July 2013

The protocol for this study was approved by the IRBs of Dartmouth College, MIT, and UCLA. We thank the Moroccan Ministry of Education and the Council for Education for their collaboration, as well as the World Bank, the Spanish Impact Evaluation Fund, the Gender Action Plan, the Korean Trust Fund for ICT4D (InfoDev), the multidonor trusts fund Governance Partnership Facility, and the Abdul Latif Jameel Poverty Action Lab at MIT for funding. We are grateful to Bénédicte de la Brière and Rebekka Grun from the World Bank for their expert support and to Claire Bernard, Nada Essalhi and Aurélie Ouss from IPA Morocco for outstanding field research assistance. We thank George Bulman, Jishnu Das, Brian Jacob, Paul Glewwe, Hongliang Zhang, and numerous seminar participants for insightful comments. The findings, interpretations, and conclusions expressed in this work do not necessarily reflect the views of the World Bank, its Board of Executive Directors, the governments they represent, or the National Bureau of Economic Research. All errors are our own.

NBER working papers are circulated for discussion and comment purposes. They have not been peer-reviewed or been subject to the review by the NBER Board of Directors that accompanies official NBER publications.

Turning a Shove into a Nudge? A "Labeled Cash Transfer" for Education Najy Benhassine, Florencia Devoto, Esther Duflo, Pascaline Dupas, and Victor Pouliquen NBER Working Paper No. 19227 July 2013 JEL No. H52,I21,I38,O15

### **ABSTRACT**

Conditional Cash Transfers (CCTs) have been shown to increase human capital investments, but their standard features make them expensive. We use a large randomized experiment in Morocco to estimate an alternative government-run program, a "labeled cash transfer" (LCT): a small cash transfer made to fathers of school-aged children in poor rural communities, not conditional on school attendance but explicitly labeled as an education support program. We document large gains in school participation. Adding conditionality and targeting mothers make almost no difference. The program increased parents' belief that education was a worthwhile investment, a likely pathway for the results.

# 1. Introduction

This paper evaluates the impact of a "labeled cash transfer" (LCT), as an alternative to conditional cash transfers for education. Ever since the pioneer PROGRESA program in Mexico in the late nineties, conditional cash transfers, or CCTs, are large in amount, targeted at poor households within a community, conditional on regular school attendance, and paid out to mothers. The program we evaluate features small transfers, targeted to poor communities (with all households eligible in those communities), and paid out to fathers.<sup>2</sup> The program is unconditional but retains an implicit endorsement of education through its school-based enrollment procedure. This program was designed and implemented on a (randomized) pilot basis by Morocco's Ministry of Education. Within the same experiment, conducted over 600 communities, we estimate the value added by typical CCT features, namely: (1) making the transfer explicitly conditional on regular attendance, (2) making payments to mothers instead of fathers, and (3) doing both at the same time.

A large body of rigorous evidence, based on CCT programs implemented around the world over the last 15 years, demonstrates their ability to affect households' investments in education and health (see Fizbein, Schady et al. (2009) for a review and Saavedra and Garcia (2012) for a recent meta-analysis). A potential drawback of CCTs as currently designed, however, is that two of their standard features, targeting (typically, individual level proxy-means testing) and conditionality, make them expensive to administer. These two features have been estimated to account for 60% of the administrative costs of PROGRESA (Caldes, Coady and Maluccio, 2006) 49% of the costs for RPS in Nicaragua, and 31% for PRAF in Honduras.

A further drawback of both targeting and conditionality is that they have the potential to lead to the exclusion of the people that policymakers would most like to aid. In Indonesia, Alatas et al. (2012a) find that a proxy-means test mimicking the government's standard practice incorrectly excluded 52% of truly poor households (based on their consumption level) from the list of beneficiaries for a large cash assistance program, while it incorrectly included 18% of non-poor households. In Malawi, under a program whose ultimate goal was to improve female adolescent health, girls who dropped out of school and lost their cash transfer eligibility transitioned into marriage and childbearing faster than comparable girls sampled for unconditional transfers (Baird et al., 2011). Furthermore, conditionality can reduce the effectiveness of transfer programs by discouraging some households to even apply for them.

<sup>&</sup>lt;sup>2</sup> In our context, paying out to father is much less constraining than paying out to mothers and is seen as the "normal" way to proceed.

Yet, both targeting and conditionality play important roles in existing CCT programs. Transfers are in part redistributive, and it would not be feasible within the budgets of developing countries to provide all citizens with unconditional transfers worth 20% of a poor household's consumption (to take the example of PROGRESA). Targeting is therefore critical. Regarding conditionality, several recent studies have shown that the incentives that conditionality (or at least perceived conditionality) give to parents may have an additional impact on educational investments, beyond the pure income effect that comes about from unrestricted cash transfers. De Brauw and Hoddinott (2011) exploit the fact that PROGRESA, due to administrative issues, made unconditional transfers to a set of beneficiaries to compare educational outcomes of both groups. They find no effect of conditionality on the likelihood that children attend primary school, but a significant difference among those making the transition from primary to secondary school. Barrera-Osorio et al. (2011) find that making transfers conditional on secondary school graduation significantly improves educational achievement. Baird et al. (2011) run an experiment to compare a CCT to a UCT (Unconditional Cash Transfer) in Malawi between 2007 and 2009. They find that conditioning cash transfers on school attendance increases the effectiveness of the program at keeping adolescent girls in school, but, as mentioned above, decreases its effectiveness at averting teen pregnancy and marriage. Also in an experiment, Akresh et al. (2013) compare a UCT to a CCT conditional on enrollment in Burkina Faso. They argue that CCTs lead to larger impacts than UCTs among girls, and initially out-of-school children, though not for boys and children already enrolled.3

Given this tension between, on the one hand, the administrative and human costs of targeting and incentives, and, on the other hand, the fact that they do play a role given the scale of existing CCTs, a natural question is whether it is possible to retain at least some of the human capital benefits of CCTs through a much more limited program. Under the standard economic theory underlying CCTs, conditionality provides economic incentives for households, but those should only have bite if the programs are sufficiently large that the households stand to lose something if they do not comply. At the same time, there is evidence that even small conditional transfers have positive effects on human capital investment (see Banerjee et al. (2010) on incentives for vaccinations, and Filmer and Schady (2008) on the impact of a small CCT in Cambodia). This suggests that economic incentives may not be the only factor at play in CCT. In other words, a "nudge" may be sufficient to significantly increase human capital investment, while CCTs as currently designed provide a big shove. By

\_

<sup>&</sup>lt;sup>3</sup> Conditionality has also been shown to matter for health behavior outcomes. Attanasio, Oppedisano and Vera-Hernández (2013) estimate that, in the Colombian program *Familias en Acción*, children would receive 86% less preventive care visits if the program was not conditional on these visits.

offering a small cash transfer and tying it loosely to the goal of education, a government may be able to make the importance of education salient and increase the demand for it even without formal incentives. A small cash transfer would not need to be targeted at the household level, since the budgetary implications of inclusion errors (giving it to less poor people) would not be large, and if the explicit incentives are replaced by an implicit endorsement, this removes the need for monitoring.

We evaluate such a program in Morocco, and test the added benefits of attaching more strings to it (conditionality and gender of the recipient), keeping the main features (small size and community targeting only) constant. We were contacted by the government of Morocco who wanted our help in conducting an evaluation of a new CCT program, Tayssir, aimed at increasing the rural primary school completion rate, which stood below 60% as of 2008. They had in mind a small transfer to households with children aged 6-15, conditional on enrollment and attendance, paid out to fathers, and targeted at the community level (meaning all households with eligible children in targeted communities could receive the transfer). The transfer amount increased with age/grade but remained modest: the average annual transfer per household equaled about 5% of their annual expenditures, compared to 20% in the PROGRESA program. We proposed to add two components to the planned evaluation: compare it to an unconditional component, and compare it to a more standard version where transfers are given to mothers. The Ministry of Education (the Ministère de l'Education Nationale, or MEN), which was administering the program, was very keen that even an unconditional form of the program should be framed as an education intervention. Thus, even for children who were not enrolled in school, the enrollment for Tayssir was done through schools, by headmasters.

Over 320 school sectors (with at least two communities each) were randomly assigned to either a control group or one of four variants of the program: LCT to fathers, LCT to mothers, CCT to fathers and CCT to mothers. Using objective measures of school participation (collected through surprise school visits by the research team) for over 44,000 children, and detailed survey data for over 4,000 households, we find large impacts of cash transfers on school participation under all versions of the program, with larger impacts for the LCTs. Over two years, the LCTs reduced the dropout rate by around 70% among those enrolled at baseline; increased re-entry by 85% among those who had dropped out before the baseline; and cut the share of never-schooled by 43%. The LCTs had modestly positive, though insignificant, impacts on math scores. While the CCTs also had a large positive effect on school participation, explicitly conditioning transfers on attendance significantly

decreased their impact in the context of this program. In particular, relative to LCTs, CCTs lowered the impact on re-enrollment of children who had dropped out, perhaps because conditionality discouraged some households (or some teachers) from enrolling weaker children in the program. Correspondingly, CCTs also had a significantly lower impact than LCTs on math scores (CCTs had no impact whatsoever, with negative point estimates). We find very little difference in impacts between transfers made to mothers and those made to fathers.

Note that the comparison between LCTs and CCTs tells us little about the question that other papers in the literature have addressed, namely how an unconditional and unlabeled cash transfer program would compare to a CCT. Instead, we study a program where transfers are not conditioned on school participation but school enrollment is strongly encouraged. Indeed, because registration for both LCTs and CCTs was done by school headmasters on the school compound, one reason behind the large impacts of LCTs seems to be that they increased the salience of education as much as CCTs. By the end of the second year, parents' beliefs about the returns to education had increased in all groups, and so had their beliefs about the quality of the local school, even though neither of these two dimensions was affected by the cash transfers. This is consistent with parents interpreting the introduction of a pro-education government program, whether it formally requires regular school participation or not, as a signal that education is important. In line with this, in all groups, there was a large reduction in dropouts reported due to "child not wanting to attend school" and to "poor school quality."

Our results also bring attention to the fact that complex government programs may not always be understood easily, and therefore some of the expected benefits of imposing rules (e.g. conditionality) can be lost in implementation. We took care in our data collection to elicit beliefs from teachers and parents regarding the rules governing the cash transfer program in their community. While teachers had a relatively good understanding of the program in their specific community, among parents we see only minor differences between CCT and LCT communities, in both years 1 and 2, in how the programs were perceived. In the first year, in both groups about 50% of the parents thought the transfers were conditional on attendance. This means that half of the parents in the LCT group wrongly believed the transfers were conditional on attendance, and half of the parents in the CCT group did not know they were. We thus cannot reject that parents in either group had no idea and just guessed when asked about conditionality. By the second year over 80% of parents in the LCT communities had understood that the program was unconditional, but most parents in the CCT communities also perceived transfers as unconditional, most likely because

absence rates are low in Morocco, and few children saw their transfers docked. Thus the gap in perceived conditionality between LCT and CCT, while significant statistically at the end of year 2, was less than 5 percentage points. This could explain why we see little impact of adding conditionality above and beyond labeling. Importantly, however, the fact that school participation impacts stayed large for both LCT and CCT programs in year 2, when a great majority of parents believed transfers were *not* conditional on attendance, implies that the confusion regarding the rules is *not* the reason behind the success of the LCT.

Overall, our results suggest that cash transfer programs may work in part by changing how parents perceive education. Of course, much larger transfers may have even larger effects on education, particularly if they are conditional and stringent (as the previous studies looking at the impact of conditionality have found). But just changing perceptions seems to be getting a long part of the way. This is consistent with the recent literature showing that the perceived returns to education are an important determinant of the demand for education, but in developing countries, information about these returns is often imperfect (Jensen, 2010; Jensen, 2012; Kaufmann, 2012; Nguyen, 2008).

To summarize, the LCT program was as effective at increasing education as traditional CCTs have been in other contexts, and cost much less. First, the transfers were small: the average household transfer represented around 5% of household consumption, compared to a range of 6% to 27% for existing CCTs in middle-income countries.<sup>4</sup> What's more, despite the small transfer amounts, the ratio of administrative costs to transfers was favorable to the Tayssir program: 10% compared to a range of 10% to 50% in other programs for which costs are documented.<sup>5</sup> Overall we estimate that the cost per extra year of education in the Tayssir program was at least 40% cheaper than it was in the education arm of the PROGRESA program. Of course, PROGRESA and other CCTs had other objectives besides increasing education, and, as such, a cost-benefit analysis focusing on education does not account for the entire value of such programs. But the comparison suggests that, for a government focused on increasing education, a LCT could be a viable option from a cost perspective.

-

<sup>&</sup>lt;sup>4</sup> World Bank Report (2009). The one exception is Pakistan, which has a transfer program for adolescent girls only amounting to 3% of household consumption.

<sup>&</sup>lt;sup>5</sup> Authors' calculations based on available information on average administrative costs over the pilot period for PROGRESA (Mexico), PRAF II(Honduras) and RPS (Nicaragua) (Caldes, Coady and Maluccio, 2006). Tayssir cost-transfer ratio is reported for a shorter period than the rest of the programs. For example, Progresa reached a cumulative cost-transfer of 10% after 4 years of implementation and 2,600,00 beneficiaries by the end of the period. During the first two years of Progresa pilot, the cost-transfer ratio represented 1.22 and 0.28 (vs 0.11 and 0.08 for Tayssir).

# 2. Background and Experimental Design

### 2.1. Background

Morocco is a lower middle income country, with a GDP per capita estimated at \$3,000 in 2011 (\$5,100 in PPP terms). Education levels in the general population are still relatively low, with only about 56% of the population literate. As of 2006, the Ministry of Education estimated that while over 87% of rural children started primary school, 40% dropped out before completing the full 6 years of primary education.

How much children learn may be limited, even if they are in school. Morocco ranked 59 out of 69 countries in the math scale for eighth-graders of the TIMMS international tests, and 64 out of 70 on the science scale. This may be due to relatively poor schooling infrastructure in rural areas, and to relatively low motivation levels among teachers, who may resent being posted in remote locations.

Despite this, "Mincerian" estimates of the returns to schooling appear large even among rural households. We present some evidence on this (based on our baseline survey data) in Appendix Table A1. Primary school completion for either the male or the female head of the household is correlated with 20% higher consumption at the household level, and these effects are additive. Of course, part or all of these correlations could be driven by selection effects.

### 2.2. Experimental Design

Tayssir was targeted at the geographic level. The pilot took place in the five poorest regions of Morocco (out of sixteen administrative regions), and within those regions, in the poorest rural municipalities (administrative units called "communes" in Morocco) with high dropout rates at the primary school level. A total of 320 rural primary school sectors (close to 65% of all school sectors in the selected regions) were sampled for the study in those municipalities. Each rural school sector has a well-identified catchment area validated by the *Delegation de l'Education Nationale*, the provincial-level authority for education policy. A school sector includes a "main" primary school unit and several "satellite" school units (four on average). Satellite units fall under the authority of the headmaster of the main unit, and sometimes offer only lower grade classes.

Figure A1 summarizes the experimental design. Out of the 320 school sectors in the study, 260 were randomly selected to participate in the Tayssir pilot program. These school sectors constitute the

<sup>&</sup>lt;sup>6</sup>The regions are Marrakech-Tensift-Al Haouz, Meknès-Tafilalet, l'Oriental, Souss-Massa-Draa and Tadla-Azilal.

treatment group. The other 60 sectors in the sample were selected to constitute the comparison group. The 260 school sectors in the treatment group were subdivided randomly into four subgroups, with a two-by-two design: conditional on attendance or simply labeled as designed to facilitate educational investments ("Tayssir" means facilitation in Arabic); and father-beneficiary vs. mother-beneficiary. The groups were not even in size: while the father vs. mother split was 50%-50%, the conditional vs. labeled only split was 69%-31%.

Two school sectors (one in the control group and one in the treatment group) had to be dropped after the randomization because floods rendered them completely inaccessible to the research team during baseline, leaving us with a final sample of 318 school sectors. Thus, we ultimately have 59 schools in the control group, 40 school sectors in the LCT-to-fathers group, 40 school sectors in the LCT-to-mothers group, 90 schools sectors in the CCT-to-fathers group and 89 school sectors in the traditional-style CCT-to-mothers group.

School sectors participating in the pilot program were selected such that they would be relatively far from each other, which limited the risk that parents transferred their children from control to treatment schools or from CCT to LCT schools, as well as other forms of externalities.<sup>9</sup>

Table 1 presents summary statistics for schools in the control sample (column 1), differences between the control group and the LCT-to-fathers group (column 2), as well as differences between the LCT-to-fathers group and the three variants with added components (columns 3-5). 10 Schools in

\_

<sup>&</sup>lt;sup>7</sup> The randomization was stratified by region, school size, dropout rate and by whether the government was planning to make improvements to school infrastructure within the two-year time frame of the evaluation.

The reason why there was more CCT than LCT schools is that, in an attempt to estimate the intensity with which conditionality needs to be monitored if it ends up mattering, each of the two CCT groups was randomly subdivided in three more subgroups of equal size. In one group, teachers were in charge of recording absences in a register that was then passed on to the central Tayssir administration determining payment amounts ("light monitoring"). In the second group, the same system was used, but to encourage accurate reporting, teachers were informed that their registers would be audited through unannounced school visits by school inspectors ("moderate monitoring"). In the third group, in addition to the teachers filling registers, biometric machines were installed in the classrooms to record child attendance daily through fingerprint recognition ("full monitoring"). In practice, neither the moderate nor the full monitoring arms could be implemented. School inspectors were reluctant to perform audits and the biometric machines proved too fragile or errorprone to be reliable. As a result, the "light monitoring" system was used to enforce conditionality in all schools in the CCT groups and we therefore lump all three subgroups for the analysis.

<sup>&</sup>lt;sup>9</sup> The median distance between any two school sectors in the regions of study is six kilometers, which is quite large considering that 99.5% of children in our sample report walking to school. The median distance between any two school sectors in the experimental sample is even larger by design.

 $<sup>^{10}</sup>$  This table follows the same format as the main regression tables below. As explained in more details in section 4, column 2 presents estimates on the differential characteristics for schools sampled in the *LCT-to-fathers* group compared to control group schools. Columns 3 to 5 present estimates on the differential effect of

the sample are relatively small, with an average enrollment in grades 1 to 5 of only 77 pupils. Over 60% of classes are taught in multi-grade groups. Only 42% of the students are girls, suggesting that girls are less likely to be enrolled than boys. Schools are quite poor, with only 19% of the classrooms equipped with electricity and just about half equipped with latrines/toilets. Overall, the control and LCT-to-fathers groups appear relatively well balanced with respect to observable characteristics: one out of 12 of differences estimated are significant at the 10% level. There are, however, some differences between the CCT and LCT groups, and some differences between father and mother groups. In the analysis, we control for the two baseline school characteristics that are imbalanced at baseline (remoteness and electricity) as well as student characteristics (age and gender). The control variables do not affect the results.

### 2.3. The Tayssir Cash Transfer Program

The Tayssir program consisted of cash payments made to parents of primary school age children (6 to 15). The cash allowance was increasing with age, starting from 60 Moroccan dirhams (MAD) per month (~\$8 in 2008 USD) per child old enough for grades 1 or 2 (6-7 years old), to 80 MAD per month (~10 USD) per child old enough for grades 3 and 4 (8-9 years old), to 100 MAD per month (~13 USD) per child old enough for grades 5 and 6 (10-11 years old). Thus for young children the cash allowance for a year (10 school months) was up to 600 MAD, and for the older children it was up to 1,000 MAD. This compares favorably to (very modest) yearly schooling expenditures, reported at 180 MAD on average per child in primary school in our control group, suggesting that the transfers were ample enough to compensate for at least the direct costs of schooling. But the transfers are very small compared to most CCTs: the monthly transfer for a child in grade 3 to 4, for example, represents 2.7% (3%) of the mean (median) monthly household consumption level in our sample (and still only 6.3% of the monthly consumption level of households at the bottom 5th percentile). The transfer that the average household was eligible for represented 5% of the average monthly consumption. In contrast, the range for traditional CCTs is between 6% and 27% of mean monthly household consumption (World Bank, 2009). In PROGRESA, the average transfer for grade 3 to grade 6 was \$14 and the total monthly average transfer received by households was \$43, which corresponds to 20% of household consumption. 11

the three other treatment groups compared to the *LCT-to-fathers* group, along with the total effects p-values for test of equality between LCT and CCT, and mothers versus fathers.

<sup>&</sup>lt;sup>11</sup> Transfer reported in Coady (2000) for 1997-2000 period, expressed in 2008 USD.

Parents had to formally enroll each of their children into the program. Headmasters, who had been trained through group-specific province-level meetings just before the start of the academic year, were responsible for disseminating information to parents of school-age children about the program and its rules, and for enrolling them. For all groups, unconditional and conditional, this enrollment took place at the primary school, and required the presence of the designated beneficiary (the father or the mother, depending on which experimental group the school sector was in). In both years, the open enrollment period started at the beginning of the school year (early September) and lasted for approximately three months. Children who had been enrolled into the program in year 1 were automatically re-enrolled in year 2 provided the school headmaster forwarded their names to the provincial authorities.

In the LCT groups, the transfer was fixed and not conditional on attendance or continued enrollment, but parents still had to enroll their child in the Tayssir program yearly in order to receive the money. While in the original design enrolling in school at the beginning of the year was not a condition for enrolling in Tayssir, in practice the two turned out to be linked: enrollment in the Tayssir program was done at school by the headmaster, and *de facto* children were systematically registered and enrolled in a grade by the headmaster at the same time they were registered for Tayssir (if not yet enrolled). (School registration is free in rural areas of Morocco). The fact that Tayssir enrollment took place at the school, even when continued school enrollment was not required to receive the transfers, is an important feature, because drawing applicants into that environment served to link the program to education. Indeed, it made it very clear and salient to households that the transfers were coming from and overseen by the Ministry of Education, and were part of an effort to promote education. The flyers that schools were given to advertise the program showed schoolchildren sitting at their school desk and studying. This is why we call this a *Labeled Cash Transfer* (LCT).

In the CCT groups, the transfer was formally conditional on enrollment and regular attendance. The rule was that the allowance for a given month and a given child would be cancelled if the child missed school more than four times over that month. Absences from school caused by the teacher's absence were excluded from this count. Headmasters, teachers and school committees received guidelines from the Ministry of Education on how to monitor and record attendance and how to submit reports every two months to the provincial-level program manager at the Ministry. The reports included, for each month, the total number of absences for each child enrolled in the program. These reports were then digitized by the provincial-level program managers, and shared,

through an integrated information system, with the central management team at Ministry of Education. The central management team determined whether the conditionality had been respected and estimated the amounts that each household should receive for any given month. This process was time-consuming and created important delays, especially early on, as described below.

Headmasters were instructed to enroll only mothers or only fathers, depending on which variant of the program the school was in. There was however an exception policy: households with a written authorization from the *Moqadem* (the local representative of the Moroccan administration) could enroll another adult in the household. Exceptions were typically granted when the sampled recipient did not live at home (for example, if the father worked in the city and came home only a few times a year, the mother was allowed to enroll instead). Overall, as we discuss below, compliance with the gender assignment was above 80%.

The cash transfers were disbursed to the assigned recipients (upon presentation of a national ID card) at the local post office. Areas that did not have a post office (about a third of the sample) received the visit of a "mobile cashier" in charge of distributing the transfers. On average, the cost of a round trip to the nearest pick-up point was around 20 MAD or 8% of the average transfer. However, if they wanted to save on transportation costs, recipients could wait and withdraw all their transfers at once.

Overall, program take-up is very high: 97% of households in our household sample had at least one child enrolled in Tayssir by the end of year 2, and the take-up rate at the household level was almost identical across all four treatment groups. Households had on average two children enrolled in the program. This is much higher than the take-up of a CCT program in Indonesia, for which poor households had to register by showing up on a specific registration day: Alatas et al. (2012b) find that only 61% of the very poorest households (those guaranteed eligibility) signed up (and the sign-up rate is lower among all income groups). The take-up rate in our household sample may be an overestimate of the overall take-up rate, however, since our household sample excludes households with no prior contact with the local school (given our sampling strategy, discussed in section 3.2). Our household sample also over-represents households living relatively close to the school. To the extent that headmasters played an important role in contacting households they knew or who lived nearby, take-up in our sample is an upper bound of overall take-up. Contrasting the administrative records on Tayssir enrollment at the municipality level with the (very noisy) data on total number of households in a given municipality as reported by the local chief (the Moqadem) confirms the

take-up rate was quite high, however, with the ratio between the two at 88% on average (with a very large standard deviation, however).

Three payments were made to enrolled households over the course of the first year. Due to delays in setting up the system for collecting and managing school attendance data, the Ministry of Education decided in December 2008 that the first transfer, corresponding to the first two months (September-October 2008), would be given to all households enrolled in the program without conditionality. For the conditional groups, the next two transfers in year 1 were conditional on attendance. In year 2, five transfers were made to households, and each transfer covered a two-month period, as per the program protocol. For the conditional groups, all those payments were conditional on attendance. To maintain comparability, each payment was made simultaneously to conditional and unconditional groups. Across groups, households qualified for just around 3,000 MAD ( $\sim 350$  USD) on average in total transfers through the first 18 months of the pilot.

## 3. Data

To estimate the impacts of the Tayssir Program, we collected detailed data on schooling achievement in two school units (the main school unit and one randomly chosen satellite unit) for each of the 318 sectors included in the study.

Four types of data were collected. (1) We measured school participation through school visits spread over the two years of the program, for all students enrolled in the study schools at the beginning of "year 0" (the academic year 2007-2008). We call this the "school sample" and it comprises over 47,000 students. (2) We conducted a comprehensive survey at both baseline and endline with close to 4,400 households – we call this the "household sample." (3) We administered a basic arithmetic test (ASER test) to one child per household during the endline household survey; and (4) We conducted "awareness" surveys at and around schools to measure teachers' and households' understanding of the program. Figure A2 summarizes the timeline of the data collection and we provide below the details for each of these datasets.

<sup>&</sup>lt;sup>12</sup> See Figure A2 for the timeline of the program implementation. The first transfer took place in late January and early February, 2009. The second transfer took place in late May/early June 2009, and it covered four months, November 2008 to February 2009. The third and last payment for year 1 covered the rest of the school year, and took place late August 2009/early September 2009.

### 3.1. School Participation

Through school visits, the research team (which had no relationship with the Tayssir team or the Ministry of Education and was blind to the assignment to the different groups) collected data on school participation. We conducted a total of seven visits per school. The first visit was announced, and conducted at baseline, in June 2008, just before the end of the pre-program school year (we call this "year 0"). During that first visit, we copied school registers for all grades 1 to 5. This register data provides the universe of children that were enrolled in school at the beginning of year 0, and whether they had dropped out or where still enrolled by the end of year 0 (June 2008, when we conducted our baseline). This constitutes our "school sample." Appendix Table A2 provides summary statistics at the child level for this school sample, broken down by treatment group. The second visit was also announced, and conducted at the beginning of the first program year. Two additional (unannounced) visits were conducted during the first year of the program (in March/April and May 2009). The fifth visit was announced, and conducted at the beginning of the second academic year. Two unannounced visits were conducted later on that year (in February and April 2010).

During each visit, we updated the schooling status of all children in the initial lists, recording who had dropped out of school and when, which grade each pupil was in (if still attending regularly), whether the teacher was present in class, and, whether the pupil was present. Names of newly enrolled students were also recorded. To analyze the impact of the program on school participation and dropout, we use data from all seven visits. However, to analyze the impact of the program on attendance, we use only data from the four surprise visits.

Attrition in this dataset (shown in Appendix Table A2) is very low since we did not need to individually track each child in the sample to obtain their schooling status, but instead relied on whether the child was found in the classroom on the day of the visit, and if not, checked registers and interviewed teachers and other students/siblings to determine whether the child had dropped out. We consider a student as a *dropout* if he or she was absent from school on the surprise visit, and was considered as dropped out by the teachers and other students. We consider a student as *attending school* if he was present on the visit day, or absent but listed on the register as enrolled for that month and having attended school at least some time in the previous 30 days.<sup>13</sup>

\_

<sup>&</sup>lt;sup>13</sup> School attendance registers were very well kept and updated. Teachers are supposed to update the list of enrolled students every month (when they have to write the names of all currently active students on a new page) and to record their presence on a daily basis. Teachers typically do not copy the name of students that

### 3.2. Household Surveys

For each school unit, eight households were sampled for a baseline survey (administered in June 2008, before Tayssir was announced and before school sectors had been randomly assigned to either treatment or control) and an endline survey (administered in June 2010). The sampling frame used to select these households was the following. Enumerators visited each school (again, these were two per school sectors, the main unit and one satellite unit) in spring 2008, and used the 2007/2008 school register, as well as the registers of the previous three academic years, to draw two lists: (1) the list of all households in the school's vicinity that had at least one child enrolled in school, and (2) the list of households with no child currently enrolled in school but at least one child of school-age who had enrolled at some point but dropped out within the previous three years. A total of six households were randomly selected from list 1, and two households were randomly selected from list 2, using a random number generator spreadsheet. This sampling method means that our sampling frame does not include households who never enrolled any school-age children in school, but such households appear very rare. (We attempted to get lists of such households from the Moqadem, but they could rarely come up with any household fitting that description, which is why systematically enrolling a few such households in the study at each location was not possible.)

Overall, a total of 5,032 households were sampled. Of them, 4832 (96%) could be interviewed at baseline. Of those interviewed at baseline, 91% were interviewed at endline. An additional 111 households that were sampled but not surveyed at baseline were found and surveyed at endline. Table A3 presents analyses of attrition at both baseline and endline. Attrition was more pronounced in the control group than Tayssir groups. To check whether this differential attrition yields imbalance in household characteristics, Table 2 presents summary statistics by group for the final, post-attrition endline sample of 4,385 households. The groups appear relatively well balanced with respect to observable characteristics. Fewer than 10% of all possible pair-wise comparisons yield differences that are significant at the 10% level. There appears to be some differences in baseline schooling rates, however. In the control group, 7 percent of children 6-15 had never enrolled and 14% had enrolled but dropped out, with the remainder (79%) enrolled. The share out of school at baseline for the LCT-to-fathers group is significantly lower, with 3.2 percentage points fewer never-enrolled and 2.7 percentage points fewer dropouts. Schooling rates for the other treatment groups

they consider as dropouts when they move on to a new page (i.e. a new month). The fact that we find a very high attendance rate of 95% (objectively measured through surprise spot checks) for those officially enrolled (on the register for that visit's month), while at the same time observing a high dropout rate, confirms that teachers truthfully report the *de facto* dropouts as dropouts.

fall somewhere in between the control and the LCT-to-fathers group. In all analyses below we condition on baseline schooling status so these baseline differences do not drive our results.

Households in the sample are relatively large, with an average of 6.8 members across all groups, including 3.1 children under 16 years old and 2.4 children in the 6-15 age group, the target group for Tayssir. Literacy rates are quite low, with only 23% of household heads knowing how to read and write. Financial access is also very low, with only 3% of households holding a bank account.

#### 3.3. ASER Arithmetic Tests

As part of the endline survey administered to study households, one child between six and 12 years old at baseline was randomly selected to take a short arithmetic test based on the ASER test developed by Pratham. This test does not evaluate children for age- or-grade specific competency. Instead, it tests the ability of children to perform basic arithmetic, such as recognizing one-digit or two-digit number, performing a subtraction, and performing a division. Of the 4,682 children sampled, only about 3,316 (71%) were available for the arithmetic test during the endline survey. Table A4 presents analysis of attrition, which was equally high across all five groups. Observable household characteristics for children who took the test are overall balanced.

### 3.4. Program Awareness Surveys

In order to estimate how much communities knew about Tayssir and its rules by the end of the first program year, a survey on "program awareness" was conducted in 387 schools in April 2009. The survey included only a few questions such as: "Have you heard of a program called Tayssir?"; "Have you been receiving transfers from the government related to your children?"; "Do you know what the transfers depend on?"; etc. The survey was administered to teachers (for each school, we attempted to survey the headmaster or deputy headmaster, as well as one grade 4 Arabic language teacher) as well as parents (for each school, we attempted to survey two households from the household sample).

A similar awareness survey was administered at the end of the second year (May/June 2010) to headmasters and teachers in all schools. We also included a module on Tayssir in the endline survey administered to study households.

<sup>&</sup>lt;sup>14</sup> See information on ASER at http://www.pratham.org/M-19-3-ASER.aspx

# 4. Empirical Strategy and Results

### 4.1. Empirical Strategy

The random assignment of cash transfers, their conditionality and their designated beneficiary across school sectors means that, in expectation, students in the control and various treatment groups have, conditional on baseline schooling status, comparable background characteristics and abilities. Thus, they likely would have, on average, comparable outcomes in the absence of any cash transfer program. By comparing outcomes between the LCT-to-fathers group and the control group, we can thus estimate the effect of the small unconditional cash transfer program we are testing. By comparing outcomes across treatment groups, we can estimate the relative importance of the various program components – conditioning on attendance and beneficiary's gender. The sample size was large enough that we are able to detect even small differences in impact across groups.

We estimate the effect of being assigned to each of the treatment groups, on the outcomes of interest, using the following specification:

$$Y_{i,j} = \alpha + \beta_1 * TAYSSIR_j + \beta_2 * LCT_{mother_j} + \beta_3 * CCT_{father_j} + \beta_4 * CCT_{mother_j} + X'_{i,j}\gamma + \varepsilon_{i,j}$$
 where  $Y_{i,j}$  is the outcome for student  $i$  in school  $j$ 

 $TAYSSIR_{j}$  is a dummy equal to 1 if school j is selected for TAYSSIR in any form (i.e., in any of the cash transfer groups)

 $\mathit{LCT}_{mother_j}$  is a dummy equal to 1 if school j is in the LCT-to-mothers group

 $\mathit{CCT}_{father_j}$  is a dummy equal to 1 if school j is in the CCT-to-fathers group

 $CCT_{mother_{j}}$  is a dummy equal to 1 if school j is in the CCT-to-mothers group

 $X_{i,j}$  is a vector of strata dummies, school-level controls (access to electricity and remoteness) and child-level controls (age, gender, schooling status and grade at baseline)

In this equation,  $\widehat{\beta_1}$  estimates the effect of unconditional but labeled cash transfers paid to the father of primary school-age children, and therefore the impact of the version of the program that has minimal strings attached (since having the father pick up the money would be the natural default in Morocco).  $\widehat{\beta_2}$  captures the differential (compared to LCT-to-fathers) effect of designating the mother as transfer recipient (while maintaining the lack of conditionality on attendance);  $\widehat{\beta_3}$  estimates the differential effect of making transfers conditional on attendance (while keeping the father as transfer recipient) and, lastly,  $\widehat{\beta_4}$  is the estimate of both making transfers conditional and paying

them to the mother. Strata dummies take account of stratification variables used in the randomization. We adjust the standard errors for clustering at the school sector level. Finally, because our sampling procedure at the household level oversampled households with dropout children, we use sampling weights in all analyses using the household survey data.<sup>15</sup>

Most tables we present estimates of equation (1) with the same format. Each row corresponds to a given dependent variable. Column 1 presents the mean of that variable in the control group (with its standard deviation in bracket underneath). Columns 2-5 present the  $\beta$  coefficient estimates and standard errors (in parentheses) from equation (1). Columns 7 and 8 present the p-values for the hypotheses that CCT has no differential impact compared to LCT and that transfers to fathers have no differential impacts compared to transfers to mothers.<sup>16</sup> We only present results that include controls for the key school and child characteristics mentioned above ( $X_{i,j}$ ), but results remain essentially unchanged when we omit those controls.

### 4.2 Compliance with, and understanding of, the experimental design

To interpret the results, it is important to check that the experimental design was actually implemented as planned. Table 3 presents summary statistics on program implementation in the four Tayssir groups.

Enrollment in the Tayssir program was high. In the LCT-to-fathers group, 97% of the households in our survey had at least one child enrolled, and 73% of the children ages 6-15 at baseline were enrolled. There is no systematic pattern by gender or by conditionality: at the child level, enrollment was a little higher in the LCT-to-mothers group and in the CCT-to-mothers group than in the other two. Compliance with the gender assignment was very high: it was close to 89% on average in schools where mothers had been designated as recipients, and around 80% in schools where fathers had been. This lower compliance rate for fathers is primarily due to the fact that men in rural Morocco sometimes out-migrate for work for part of the year. Overall, though, fathers were over 75% more likely to be Tayssir recipients in the father groups than in the mother groups; therefore our study is powered to detect even small impacts of the designated gender of the recipient.<sup>17</sup>

<sup>&</sup>lt;sup>15</sup> Our final household sample includes 17% of households with dropout children, while those households represent only 9% of the population.

<sup>&</sup>lt;sup>16</sup> Note that the test in column 8 weights the impact of gender on CCTs three times as much as the impact of gender for LCTs, since in our experiment the CCT group was three times larger than the LCT group.

<sup>&</sup>lt;sup>17</sup> One could be concerned that the money, while handed to the mothers, was directly appropriated by the father. To test this, Table 3 also checks whether the designated recipient picked up the cash transfer alone. We

Compliance by the Tayssir staff with the transfer rules was high as well. Administrative data shows that, after the first transfer that all households got unconditionally, all subsequent transfers made to parents in the CCT groups were a function of attendance records, while none of the transfers in the LCT groups were. As a result, households in the LCT groups received more money over the lifetime of the program (though the difference is not very large, given that overall compliance with the conditionality was extremely high in the CCT groups).

Among local communities, conditionality appears to have been poorly understood, however. In Table 4, we present data on understanding of the program in both years. While teachers were quite well informed on the exact amounts of the transfers for various age groups, there is at most a 20 percentage point difference in the beliefs that transfers are conditional on attendance between teachers in the CCT and those in the LCT groups (Panel A). While this difference is highly significant, it is quite far from the 100 percentage point difference we would have expected under perfect understanding. Over the course of the program, understanding improved among teachers. By the end of year 2, close to 75% of teachers in CCT schools believed transfers were conditional on attendance, against only 40% in LCT schools.

Our measure of understanding of parents is, unfortunately, not perfect (it is very difficult to ask parents neutral (non-leading) questions about their understanding of the rules, and be sure that they have actually understood the questions), but the data we have suggests that parents were confused. There was no apparent difference in beliefs about the conditionality between CCT and LCT groups at the end of year 1 (Panel C), with just about 50% of parents in all groups thinking that the transfers were conditional on attendance (so parents may just have been taking a guess when answering the survey). By the end of year 2, confusion had cleared in the LCT communities, with over 80% of parents knowing the transfers were not conditional. <sup>18</sup> But the dominant belief in the CCT groups was also that transfer amounts were *not* conditional on attendance. This could be because, as we will see, school attendance happens to be very high in Morocco, conditional on enrollment. Most households in the CCT groups therefore ended up getting the full transfers, and had no experience of what would happen if the children were absent a lot. What's more, as shown in Figure A2, government delays meant that transfers arrived in lumps of different sizes (from 2 to 4

find that 33% of designated mothers picked up the transfer alone (compared to 70% of designated fathers). 14% of designated mothers were accompanied by their husband when they picked up the transfers, and 40% were accompanied by another household member.

 $<sup>^{18}</sup>$  In the LCT group, program officers visited individual households at the end of year 1 to re-iterate that they only needed to enroll their children in Tayssir at the school to get the transfer every month.

months worth) with a delay of at least 3 months – making it difficult for parents to infer the rules by themselves.

The relatively poor understanding of the CCT rules among intended beneficiaries is an important outcome in and of itself. Indeed, at the beginning of each school year, a real effort was made to try to make communities (who were the ones in charge of enrolling parents) understand the rules of the program. Each school director received instructions and handouts explaining the rules specific to their school sector. If, despite this, parents only have a dim sense of what the program rules are and the extent to which they're enforced, the role conditionality plays in providing incentives is necessarily blunted. This relates to a recent paper by Kaufmann et al. (2012): studying a CCT program in Brazil in which conditionality is strictly enforced, they find that child attendance increases once households get formal warnings that their child's absenteeism threatens their standing in the program, and increases even more after the households start being punished. This highlights the role of perceptions in the role that incentives can play in CCT. This is an important point since timely enforcement of conditionality, and therefore their proper understanding, is likely to be difficult to achieve in many settings.<sup>19</sup>

### 4.3 Results: Impacts on School Participation

Table 5 shows the main results on school participation. We present the results obtained from two separate sources: the household surveys (Panel A) and the school visits (Panel B), finding very consistent results across the two sources.

Starting with the household sample, the first row of the table shows the main result: the impact of the program on school participation at the end of year 2 among all primary-school aged children in the household sample, irrespective of status at baseline (but controlling for schooling status at baseline). School participation is a dummy equal to 1 if the child was reported as having attended school at least once in the last month of program year 2. The effect is very large. We find that school participation is 7.3 percentage points higher in the LCT-to-fathers group than in the control group.

<sup>&</sup>lt;sup>19</sup> Evaluations of cash transfer programs so far have not systematically collected data on program comprehension, so comparing the level of understanding in our setting with that in others is difficult. In particular, Akresh et al. (2013) do not report perception of conditionality by parents in their program. Baird et al. (2011) look at the perception of the conditionality among adolescent girls receiving a UCT by conducting qualitative interviews. They report a good understanding of the program rules (i.e. of the fact that no condition is required to receive the transfer), but they also provide evidence that girls in the UCT arm had friends in the CCT arm and knew the school attendance of these friends was monitored, putting the UCT in the broader context of an education program.

This corresponds to a decrease in non-participation of around 30 percent. It is much larger than the impact of the first CCT, PROGRESA, at the primary level, at least in part because attrition from primary school is a larger problem to start with in Morocco than in Mexico. The effect is similar regardless of the gender of the recipient (father/mother) but 2 percentage points *higher* (significantly so) under the LCT than under the CCT program.

The next rows provide a breakdown of the school participation effect by baseline school participation status. We find that both the dropout and the re-enrollment margins are affected. In the household sample, the dropout rate diminishes by 75% under the Tayssir program, no matter how it is implemented (a drop of 7.5 percentage points, off of a base rate of 10% in the control group). In the much larger school sample (Panel B), the results are very similar: dropout declines from 7.6% in the control group to about 2.5% in all the Tayssir groups. The consistency between the self-reported participation data in the household survey and the school sample results (which are based on direct observations in classrooms during spot checks) is important and implies that parental reports of child participation were truthful.

The household data also shows that re-entry almost doubles in the LCT groups (from 14.7% in the control group to 27.2% in the LCT-to-fathers group). In the CCT group, the effect is still large, but significantly smaller. The re-entry difference is the source of the greater overall impact on school participation of the LCT compared to the CCT.

Since CCT is conditional on attendance, while LCT is not, it is important to check the impact on attendance. The results of surprise attendance checks are presented in row 4 of Panel B (for the school sample). Note that attendance conditional on enrollment is a selected outcome, since the program affects dropout, and this would bias us against finding positive impact on attendance. Attendance of enrolled children is very high overall during the periods covered by our unannounced spot checks (February, March and May). The mean attendance rate of 95.5% in the control group corresponds to an average of 1.1 days of absence per month, well below the threshold of four absences imposed on students in the CCT arm. Attendance in the LCT group is, if anything, higher than in the control group, though not significantly so. The LCT impact on school participation that we found in the household survey data thus translates into effective participation in school, and it is definitely not the case that parents enrolled their children in school just to get enrolled with Tayssir and did not bother to send them to school very regularly afterwards.

If children spent more time in school, what did school participation crowd out? We collected hour-level time-use data for the day preceding the endline survey for every child aged 6-15 at baseline. Table 6 presents results from this data, restricting the sample to the 25% of households interviewed before the summer school break started. (We don't present the four versions of the Tayssir program separately, as the sample size is too small to detect small differences between them, but we find no systematic patterns.) Looking first on the extensive margin of school participation, we find a large impact of the Tayssir transfers, with children of program households over 50% more likely to have attended school the day before the survey. This is a much larger effect than that observed in Table 5, and suggests that the program has much more bite in the very last weeks of school before the summer break – a period during which both pupils and teacher attendance appears much spottier than the rest of the year.

Correspondingly, we see a large increase in the time children spent in school-related activities in the day before the survey (this includes the time spent in school as well as time doing homework and participating in extracurricular activities organized by the school). In Tayssir groups, children spent about an extra hour and a half on average in school-related activities in the day preceding the survey compared to 2.5 hours spent by children in the control group. Overall, the magnitude of the time use results in Table 6, when compared to those in Table 5, suggests an important intensive margin effect in addition to the extensive margin effect: children in the Tayssir groups spend more time studying and more time physically at the school, as well as more time traveling to and from school, *conditional* on being enrolled. This extra time spent on learning did not come at the expense of time spent on chores, but in a small part at the expense of household farming or business activities and in a larger part at the expense of what we call leisure: play and social activities. This suggests that children had time to spare invest in education and thus, in this environment, the barrier to schooling may have had more to do with lack of interest than with severe constraints.

### 4.4 Results: Impacts on Basic Math Skills

Few studies of conditional cash transfers have measured learning outcome among school-age children, but when they have, they found no effects, despite increases in participation (Behrman et al., 2005; Filmer and Schady, 2009). This is line with many other studies that have been effective at increasing school participation but have found little impact on learning (see Glewwe and Kremer,

<sup>&</sup>lt;sup>20</sup> The initial plan was to interview all households before the school break, but the start of the endline survey was delayed due to logistical constraints. We have the same proportion of households surveyed before the school break in all groups.

2006, and Glewwe et al., 2012, for reviews), which raises some questions on the value of promoting school participation without some improvements in school quality. To be able to test the underlying premise behind the Ministry of Education's plan for a cash transfer program, we collected a simple measure of learning achievement, the ASER arithmetic test, that could be administered at home, and thus does not suffer from sample selection due to differential school participation rates across groups. Table 7 shows the impact on performance on the test, which as administered to one randomly selected child per household during the endline survey. Panel A show the results question by question for all children, as well as results on a standardized measure of achievement on the test, and Panel B presents the standardized measures by gender, school type and baseline enrollment status. There is a modest positive impact of LCT-to-fathers on standardized test scores (0.075, which rescaled amounts to 0.075/0.694=0.11 or 11% of a standard deviation in the control group), which is not quite significant in the overall sample (although it is larger and significant for students enrolled at baseline and those from satellite school units).

Interestingly however, here again we can rule out equality of the LCT and the CCT impacts: the CCT had significantly *smaller* impacts than the LCT. In fact, even a small positive effect of the CCT program (over the control group) can be ruled out. The difference between CCT and LCT is significant at 5%. This is consistent with the participation results, and suggests that LCTs are, if anything, more effective than the CCT in this context.

### 4.5 Results: Who did the program affect most?

Akresh et al. (2013), who compare a purely unconditional cash transfer and a CCT program in Burkina Faso, fond insignificant differences on average between the programs, but argued that the UCT had smaller effects than the CCT on more "marginal" children: girls, out-of-school children, and children of lower ability. To investigate this question in our context, Table 8 shows the main impact of LCT-to-fathers and the effect of all the other versions of the program for these different subgroups (and Panel B of Table 7 presents the subgroup results on learning).

Possibly because we consider a *labeled* unconditional cash transfer program rather than a pure UCT, our results differ from those found by Akresh et al. (2013). First, as mentioned earlier, the impact of the Tayssir LCT on re-enrollment rate for children who had dropped out is significantly *larger* than the impact of the CCT. Second, although girls have a lower education level than boys (67% of girls aged 6-15 were in school at the end of year 2, against 80% of boys), the LCT does not have a smaller effect on girls than boys. In fact, if anything it appears that girls are driving the larger impact of LCT

than CCT on re-enrollment: for girls initially dropped out school, the increase in re-enrollment in the LCT-to-fathers group is 12 percentage points and is significant, in the LCT-to-mothers it is 12.8 percentage points and significant, but it is zero in the CCT-to-fathers groups and only 4 percentage points) in the CCT-to-mothers group. The difference between LCT and CCT for these girls initially out of school is significant at 1%.

In the last two columns of Panel A, Table 8, we break down the children in the household sample based on their predicted probability of school participation. This predicted probability is constructed using coefficient estimates of enrollment status on school-level, household-level and child-level characteristics in the control group (these coefficient estimates are shown in Table A5). Not surprisingly, we find that all the program effects on school participation are concentrated among those with a predicted likelihood of school participation below the median. And for those, the effect of the CCT is significantly smaller (3.6 percentage points, or 23% lower) than that of the LCT. This result, while important in itself, also confirms that despite poor understanding by parents of the specific rules of the programs, it is *not* the case that the LCT and CCT programs were completely equivalent in practice – if they were, we would not see any difference in impacts.

# 5 Mechanisms

The main findings so far are that the Tayssir program, which provided small transfers to parents to help with the education of their children, had a large impact on school participation, both through reducing dropout and through encouraging re-enrollment. Further, attendance is very high for all children who are enrolled, so this increase in enrollment translated into real gains in schooling, although we do not find large impacts on learning. The second important finding is that there is essentially no difference between transfers to fathers and mothers (and there was very good enforcement of the gender of the recipient). The third finding is that the LCT has a significantly larger impact on school participation (mostly through higher re-enrollment). In this section we provide some additional evidence to shed light on the mechanisms behind these results.

### 5.1 Making Education Salient

Figure 1 shows the dropout rates by cause in the control group, and how they were affected by the program (we only show all the Tayssir groups together for brevity, but there was no significant difference across any of the groups). In the control group, the three main reasons for dropping out of

school are accessibility of the school ("school is too far"), financial reasons, and the fact that the child did not like school ("child's choice"). Tayssir was not designed to affect distance to school and, not surprisingly, did not reduce dropout rates due to distance. In contrast, it reduced the incidence of dropouts due to financial difficulties, though this effect is not quite significant at conventional levels (the p-value is 0.123). Interestingly, Tayssir had an even larger impact on dropouts due to children simply not wanting to be in school. Also, dropouts due to the belief that school is of poor quality were also considerably reduced by Tayssir. This is surprising, since Tayssir was not accompanied by improvements in school quality and did not include any transfers to schools, therefore leaving school infrastructure quality unchanged.<sup>21</sup> If anything, the increase in school participation in those schools may have lowered quality, to the extent that class size matters.<sup>22</sup>

One conjecture is that the program, which gave teachers the crucial role of enrolling households, was perceived as an implicit endorsement of the local schools by the Ministry of Education. Table 9 provides further evidence for this. Parents in schools sampled for the Tayssir program, irrespective of which variant of the program they are in, rank the school quality significantly higher.

Parents may also have interpreted the introduction of a program sponsored by the Ministry of Education as a positive signal about the value of education more generally. Consistent with this, the evidence in Table 9 shows that parental beliefs regarding the returns to education dramatically increased, especially for girls. For girls, the cash transfer programs led to very large positive changes in the perceived returns to education. In the control group, parents point estimate of the returns to primary school for girls is actually negative. There is a large increase in the Tayssir group, and it becomes positive. The perceived returns to secondary school are more than twice as large in the Tayssir group as in the control group. This is driven by changes on the extensive margin – parents in the Tayssir group believe the likelihood of getting employed is higher with primary or junior high school education than parents in the control group. For boys, the effect is small at primary school, and large but not significant at the secondary school level.

-

<sup>&</sup>lt;sup>21</sup> Within the two-year time frame of the Tayssir pilot, there were improvements in school infrastructure through an emergency plan put in place by the Ministry of Education, but, as explained in Section 2.2, we were able to stratify by whether a school was scheduled to receive infrastructure support when randomly assigning school sectors to experimental arms.

<sup>&</sup>lt;sup>22</sup> We can also rule out the possibility that the Tayssir program increased teacher effort or motivation. Overall, we find no program effect on teacher absenteeism. Teachers miss about 10% of school days in control schools, which corresponds to an average of 2.5 days in a given month. Teacher attendance was unaffected by the introduction of Tayssir in any form.

<sup>&</sup>lt;sup>23</sup> We observe this increase in perceived returns among both types of households in our sample (those sampled from the list of enrolled children and those sampled from the list of recent dropouts). The increases are similar in all versions of the programs, so we pool here for precision.

Did Tayssir make parents over-optimistic about education? As mentioned earlier, Appendix Table A1 reports estimate of the "Mincerian" returns to education in our sample. The increase in household consumption when a female has completed primary education is actually much larger than what even household in the Tayssir groups estimate (parents underestimate the returns to primary education), though this may in part due to selection bias, of course.

Several studies (Jensen, 2010, 2012; Nguyen, 2008) have shown that parents respond to interventions that increase the perceived returns to education by increasing participation and effort in school. Although the Tayssir program was not focused on persuading parents of the returns to education, the impact on the perceived value of education was actually larger in our intervention than in those ones and, as in those, we find an increase in school enrollment.

### 5.2 Is a nudge all that is needed?

To the extent that conditionality had any impact, it was a negative one: the LCT impacts on overall school participation and learning were slightly stronger than the impacts of the CCT. As mentioned in the introduction, this result differs from those of previous studies, which tend to find positive impacts of conditionality, at least for some subgroups (see Baird et al. (2011) and Akresh et al. (2013) for two experiments). This is likely because, while the transfers were not conditional on attendance, Tayssir was quite explicitly framed as an education program: headmasters were conducting the enrollment into the program, and the enrollment took place in schools. Thus, while unlabeled unconditional transfers may be less effective at increasing school participation than transfers tied to education, and while strict enforcement of conditionality seems to have additional impact on attendance (Kaufmann et al., 2012), unconditional but labeled transfers such as the one piloted in Morocco may well provide the nudge that is sufficient to convince parents to send their children to school. While we have not experimented with larger transfers or with finer targeting, it seems that a small transfer targeted only through at the community level was sufficient to achieve a large impact. Thus, the big shove that is provided by the CCT may not be necessary to substantially raise school participation.

In the Moroccan context at least, the nudge has a number of advantages over the shove. First, it is substantially cheaper, both because the transfers per child are smaller and because the administrative costs are lower. If one considers that transfers are not costs (only the deadweight loss of raising the funds for them is a cost), the point is even stronger, because the administrative costs of Tayssir are a fraction of those of the traditional CCT. Table 10 presents a cost-effectiveness

analysis of the program. The overall cost of the LCT was \$99 per child per year (in 2008 US dollars, \$89 in transfers and \$10 (7%) in administrative costs). Compared to the three earlier CCT programs presented in Table 10, Tayssir LCT has the smallest cost-transfer ratio, even relative to PRAF II in Honduras which had mainly a geographical targeting and small transfers (of 4% of household consumption). The cost-effectiveness comparison also favors Tayssir: for the Tayssir LCT program, \$1,000 led to an increase of 0.24 years of education at the primary level -- in other words, the cost of an extra year of education is \$4,228 in the Tayssir LCT program. For PROGRESA, the cost of an extra year of primary education induced by the CCT is at least 70% higher.<sup>24</sup>

The second advantage of the nudge over the shove in our context is that the LCT had actually larger impacts on enrollment and days spent in school than the CCT. This comes from the marginal children – those with a lower propensity to be in school absent any transfers. One likely explanation for this result is that, for people who understand it, the conditionality on attendance may be discouraging: someone who feels like they will not manage to have less than four absences a month may either not enroll or give up under a CCT, but continue under the LCT. Parents in our study context seemed relatively confused about the rules governing the CCT, but this effect could also have come about through the teachers themselves. Indeed, teachers were much more likely to have understood the conditionality, and it is possible that in conditional schools they did not bother to actively seek and enroll into Tayssir the parents of students whom they feel would not regularly attend. Since pupil absenteeism is not a big problem, the incentives based on attendance may thus have discouraged students to enroll without having much bite for those enrolled anyway, making the LCT a better alternative in this context.

Finally, while we did not explicitly compare different ways of targeting households, the very large take-up of Tayssir points to a very important advantage of the geographical targeting used in this study. Indeed, in Indonesia, Alatas et al (2012b) find that in a proxy-means tested program where eligible households must sign-up on their own to enroll and receive benefits, many poor eligible households do not actually sign-up. By removing any ambiguity on eligibility, and putting the responsibility of enrolling households on the teachers, the geographical targeting in the Tayssir program was able to eliminate this problem to a large extent (although as we just discussed not all *children* enrolled, and some vulnerable children may have been left out in the CCT).

 $<sup>^{24}</sup>$  Coady (2000) estimates the cost of an extra year of primary education, for Progresa, at 55,000 pesos (in 2000 pesos), which is equivalent to around \$7,300 (in 2008 USD). Dhaliwal et al (2013) estimate an even higher cost per year of education for Progresa.

# 6 Conclusion

Through a large-scale randomized experiment conducted jointly with the Moroccan Government, we show that a cash transfer labeled for education and made to households of primary school age children in rural areas had a very large impact on school participation –despite the fact that the transfer was not conditional on attendance, was given to fathers rather than mothers, and was relatively small – enough to cover the direct costs of education but very small relative to most earlier CCTs as a share of household consumption, even for the poorest households in our sample. These strong results are due in part to an endorsement effect: parents update upwards their beliefs about the value of education when a large pro-education government program enters their community. The cash transfer was labeled for education purposes, since it was coming from the Ministry of Education, and enrollment for the program was administered by school headmasters. In this context, adding formal conditions on attendance tends to decrease the overall impact on participation and learning, and targeting the program to mothers makes no difference.

In a context where pupil absenteeism (conditional on teacher's presence) is negligible for most of the school year, this labeled unconditional cash transfer (LCT) is more cost effective than the standard CCT, both because it requires transfers of lower amounts (which may not be counted as costs anyway) and, more importantly, because the administrative costs are much lower. Even in our setting, the administrative costs are reduced by more than one fourth in the LCT version compared to the CCT, and the conditionality slightly lowers the effect and worsens the targeting. We note that our context is not unique: in Burkina Faso, Akresh et al. (2013) find similarly low rates of absenteeism among enrolled students. In Kenya, Duflo et al. (2012) also find very low rates of absenteeism among lower grade students conditional on teacher's presence.

A key question is whether LCT impacts would persist in the long run. To the extent the impacts are due to an increased estimate of the returns to education, long-run impacts will be hampered if the program leads parents to temporarily overestimate those returns. Overoptimistic parents should revert back to their previous levels of investment once they realize that their child's education has not delivered what they had hoped it would. In our survey data, however, parents appear to still underestimate the returns to education, even after the introduction of the program, suggesting that this disappointment effect will be unlikely.

Notes: Data sources: Panels A-C: Knowledge surveys administered to a subset of school teachers (including school directors) and households. Panel D: Endline survey administered to all households sampled for the study. Weights are included in Panel C to get a sample representative of households surveyed at baseline. Sampling weights are used in Panel D since households with dropout children were over-sampled.

Column 1: Standard deviations presented in brackets. Column 2: coefficients and Standard errors (in parentheses) from an OLS regression of the left-hand side variable on a dummy for the Conditional Treatment dummy, controlling for strata dummies and variables specified below. Standard errors are clustered at the school-sector level. \*\*\*, \*\*, \* indicate significance at 1, 5 and 10%.

Panels A and B controls include: respondent gender, respondent status (teacher or headmaster) and school-level controls for access to electricity and remoteness. Panel C controls include: school-level controls for access to electricity and remoteness, and household level controls for share of children enrolled in school at baseline and household owns a cellphone.

Notes: Data source: Panel A: Household survey collected from study households; unit of observation: child; average of 2.5 children per household; sampling weights are used since households with dropout children were over-sampled. Panel B: School visits data; unit of observation: child (rows 1,2,3, 5 of Panel B) and child-day (row 4 of Panel B).

Each row presents the results of a separate regression. Column 1: Standard deviations presented in brackets. Columns 2-5: coefficients and standard errors (in parentheses) from a LPM regression of the left-hand side variable on treatment dummies, controlling for strata dummies and variables specified below. Standard errors are clustered at the school-sector level. \*\*\*, \*\*, \* indicate significance at 1, 5 and 10%.

Panel A: School-level controls include: access to electricity and remoteness. Household controls include: share of children enrolled in school at baseline and household owns a cellphone. Individual controls include: age, gender and schooling status at baseline (end of year 0)

Panel B: Individual controls include: age, gender, schooling status and grade the child attended at the end of year 0; school-level controls include access to electricity and remoteness. The regression on attendance also control for the day of the visit.

 $<sup>^\</sup>dagger$  Dropout during year X include dropouts in the summer between school year X-1 and year X, as well as dropouts in the course of year  ${f v}$ 

Table 6. Daily Time use

	Mean in Control Group	Effect of Tayssir (any type of treatment group)	N

Other activities (not doing anything, walking (not to school))	58 [81.72]	-3.71 (8.37)	1227

Notes: Data source: Endline household survey. Unit of observation: Child. Sample is restricted to 554 households interviewed before the summer school break started (June 15, 2010).

Column 1: Standard deviations presented in brackets. Column 2: coefficients and Standard errors (in parentheses) from an OLS regression of the left-hand side variable on Tayssir dummy, controlling for strata dummies and variables specified below. Standard errors are clustered at the school-sector level. \*\*\*, \*\*, \* indicate significance at 1, 5 and 10%. Child controls include: age, gender, schooling status and grade in year 0 (if any) and day of the week the survey was administered. All regressions also include household- and school-level controls as in Table 5 Panel A. Sampling weights are used since households with dropout children were over-sampled.

<sup>&</sup>lt;sup>a</sup> This category consists of 7 sub-activities pre-specified in the survey under the header "leisure/social activities": social and religious activities; social celebrations; playing with other children; visiting family or neighbors; playing sports; watching TV; using the internet or playing video games; and playing at home.

Notes: Data source: Endline household survey. Sampling weights are used since households with dropout children were over-sampled. Unit of observation: Household. Column 1: Standard deviations presented in brackets. Columns 2: coefficients and Standard errors (in parentheses) from an OLS regression of the left-hand side variable on treatment dummy, controlling for strata dummies and variables below specified. Standard errors are clustered at the school-sector level. \*\*\*, \*\*, \* indicate significance at 1, 5 and 10%. All regressions include same household- and school-level controls as in Table 5 Panel A.

<sup>†</sup> Average across 3 school quality indicators. Coded so that 4 reflects highly satisfied, 3 satisfied, 2 disatisfied and 1 highly disatisfied. The 3 indicators are: infrastructure quality, headmaster availability and teacher quality.

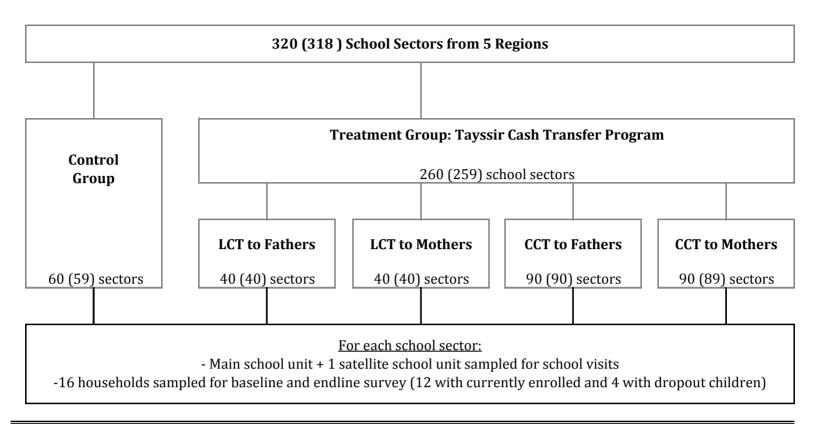

<sup>‡</sup> Respondents were not asked for a probability between 0 and 1. They were asked to choose between five categories (no chance, few chances, 50% chance, lots of chances, and certain chance). We impute probabilities of 0, 0.25, 0.5, 0.75 and 1 to these categories, respectively.

Table 10. Program Costs and Cost-effectiveness analysis

	TAYS	SSIR	PROGRESA/ OPORTUNIDADES	PRAF	RPS
	CCT	LCT	Mexico	Honduras	Nicaragua
Ratio administrative costs-transfers(a)					
Year 1	0.158	0.119	1.223	0.664	2.107
Year 2	0.11052	0.082	0.280	0.226	0.405
Year3	-	-	0.082	0.163	0.331
Year 4	-	-	0.049	-	-
Cumulative	0.133	0.100	0.106	0.325	0.489
Average	0.134	0.101	0.409	0.351	0.948
Household coverage by the end of the studied period	52,0	000	2,600,000	47,800	10,000
Cost-effectiveness (in 2008 USD) (b)					
Administrative cost per child per year	13	10			
Transfer cost per child per year	85	89			
Total cost per child per year	98	99			
Cost per extra year of education (in 2008 USD) (c)	4,043	4,228	7,300		
Extra years of education per USD 1000 spent	0.247	0.237			

Notes: (a) Sources: Tayssir: own calculations based on admin data and estimates provided by the program. Progresa, PRAF and RPS cost-transfer ratio: Cortes, Coady and Maluccio (2006), excluding impact evaluation costs. (b) Average per child per year over the 2-year pilot period of Tayssir. Source: own calculations. (c) Tayssir: Computed as present value of total cost divided by present value of extra years of education, over the 2-year studied period. Progresa: estimate from Coady (2000).

Figure A1: Experimental Design

Notes: Sample size X (Y) indicates the initial (realized) sample size. The realized sample size is slightly smaller than the initial sample size due to 2 school sectors that couldn't be reached at baseline due to floods.

CCT stands for Conditional Cash Transfer. The condition was "no more than 4 absences in the month". LCT stands for Labeled (unconditional) Cash Transfer. See section 2.3 of paper for details on the amounts of the transfers.
